

Hyrox Race Report

Avinash Kudpaje & Kavya Murthy

Mixed Doubles • Bengaluru • Season 8 (2026)

Finish 1:51:36

Overall rank	Age group	In age group	Field percentile
294 of ~547	40–44	30 of 62	54th

Running 54:45 (rank 177) • Stations 46:11 • Roxzone 10:46 (rank 317) • Best km 5:34 (rank 87)

This is a full breakdown of one race: Avinash Kudpaje and Kavya Murthy’s mixed-doubles run at Hyrox Bengaluru in Season 8. In a mixed team the two partners run all eight kilometres side by side and divide the eight stations between them however they choose, with the clock recording one shared time. They crossed the line in **1:51:36**, which placed them **294th of roughly 547 teams**, 30th of the 62 teams in the 40–44 age group, and within ninety seconds of their event’s median. The pages that follow look at the result from five angles: where the finish sits against the local and world fields, which segments carried it and which held it back, how many actual minutes each segment cost against a fair benchmark, how the running was paced, and what a targeted winter of training would plausibly have been worth. The full split sheet closes the report.

One methodological note up front. Mixed-doubles results in the public archive carry no split times, so this report combines their own detail sheet, which does, with two reference fields drawn from the archive: their complete Bengaluru event (finish times for all 547 teams) and the Bengaluru men’s and women’s doubles fields, whose 800-plus split records provide the fairest available benchmark for what a median local doubles team does at each station.

1 Where the finish sits

A finish time never means anything on its own; it means something against a field, and Figure 1 shows this one against two. Against their own event, the blue distribution, 1:51:36 lands almost exactly on the median of 1:50:12. Half the teams in the hall that Sunday were ahead of them, half behind, and the event winner, at a remarkable 55:18, was racing a different sport entirely. Against the worldwide mixed-doubles field, the grey distribution, the same time sits deep in the back half, because the global median for a mixed team is 1:21:42, essentially half an hour quicker.

That thirty-minute gap deserves a careful reading, because it says more about Bengaluru than about this team. Bengaluru joined the Hyrox calendar in Season 8; its field is composed almost entirely of first-timers, and first-timers finish where first-timers finish everywhere on earth. The main report’s India analysis found the same pattern across every Indian venue, and found that it is a timestamp rather than a ceiling: every mature Hyrox market once looked exactly like this, and the median falls quickly as a market’s athletes accumulate starts. For personal goal-setting, the blue curve is the honest yardstick today. For ambition, it is worth knowing that even Mumbai’s mixed field, one season older, already runs a median of 1:43:25, seven minutes ahead of Bengaluru’s. The market itself will get faster around them; the interesting question is whether they get faster faster.

Figure 1: Their 1:51:36 (red line) against their own Bengaluru event and the global mixed-doubles field. The local median is 1:50:12; the world median is 1:21:42.

2 Segment by segment: a runner's profile

The single most informative view of the race is Figure 2, which ranks every timed segment within the event. The dashed line marks their overall finishing rank of 294th. Everything green outperformed that rank and pulled the result upward; everything red underperformed it and dragged the result down. Very few athletes produce a chart this cleanly divided, and the division runs exactly along one line: locomotion against load.

On the green side, their best single kilometre ranked 87th in the whole field, their total running 177th, and the two aerobic stations follow the same logic: the row, which is closest in character to running, ranked 206th, and the burpee broad jumps, which are as much engine as strength, 288th. On the red side sit every station where something heavy has to be moved: the sled pull at 484th, within the slowest sixty teams of the whole event, the sandbag lunges at 471st, the wall balls at 466th, the farmers carry at 437th and the SkiErg at 436th. In the language of the main report's archetype analysis, this is the textbook "runner with weak stations" quadrant, and the report's million-result finding about that quadrant applies directly here: the sport taxes imbalance, and the fastest route up the field is almost never to sharpen the strength further but to raise the weakness toward it.

It is worth pausing on why this is genuinely good news. Running endurance is the slowest quality in fitness to build, often taking years of consistent volume, and they already have it. Sled work, grip strength and wall-ball capacity are among the fastest qualities to build, responding to weeks and months of targeted work. Their hardest asset is already banked; what remains is the trainable part.

Figure 2: Rank in the event for each segment. Green beats their overall 294th; red trails it. The profile splits cleanly into running strength and station weakness.

Figure 3: Their team's position on the global athlete archetype map. The background density shows all global results, with their position plotted relative to the local benchmark (Bengaluru doubles medians) and the global doubles benchmark.

3 Minutes, not ranks: the local benchmark

Ranks tell you where the problems are; minutes tell you what they cost. Figure 4 converts each segment into minutes gained or lost against the median Bengaluru men's or women's doubles team, the fairest split-level benchmark the data offers, since those teams raced the same stations in the same hall on the same weekend.

» They out-ran the local doubles median by 3.6 minutes and matched it on the row, but gave back about 13 minutes across the strength stations and transitions, which is the whole story of the result.

Figure 4: Each segment in minutes against the median Bengaluru doubles team. They beat the local median outright on running and the row; the strength stations and transitions gave the time back.

The headline on the green side is striking: **they out-ran the median local doubles team by 3.6 minutes** (54:45 against 58:22) and edged it on the row as well. Against the same benchmark, though, the strength stations returned all of that and more: 3.8 minutes lost on the wall balls alone, 2.8 on the lunges, 2.6 on the sled pull, 1.2 on the sled push, with smaller losses on the SkiErg, farmers carry and burpee jumps, and about a minute in the roxzone. Add up the red bars and roughly **thirteen minutes** separate this team from a race in which every station merely matched the local median, while the running stayed exactly as it was. Thirteen minutes is not a rounding error; in this event it is the difference between the median and the top third of the field, as the final section shows.

The time-budget view makes the same point from a different angle. Their race divided into 49 percent running, 41 percent stations and 10 percent transitions. A typical doubles team worldwide spends about 57 percent of its race running and only 35 percent at stations, precisely because the stations, done well and shared between two people, should be quick. When the station share of a doubles race climbs toward that of a solo race, as it does here, it is the signature of a team whose station work has not yet caught up with its engine.

4 The eight runs: a rare negative split

Because the engine is their weapon, the running deserves a closer look, and it contains this race's most impressive hidden statistic. Figure 5 plots all eight kilometre laps. Their first four laps took 27:26 and their last four 27:23: they ran the second half of the race **faster** than the first.

In the main report's analysis of nearly a million races, only about one athlete in nine manages a negative split, and those who do finish a median eight percentile places higher than the rest. Whatever else happened in this race, the discipline that most of the sport lacks, restraint in the opening kilometres, was present here.

Figure 5: The eight 1 km laps. Green marks the fastest, Run 2 at 5:34. The halves came in at 27:26 and 27:23, a negative split that only about one team in nine achieves.

Inside that even envelope, the laps themselves swung considerably, from 5:34 at best to 7:53 at worst, a lap-to-lap variability of about 13 percent where the sport's most efficient racers hold 5 to 6. The pattern of the slow laps is not random: Runs 3 and 4, the two slowest, bracket the sled block, and Runs 7 and 8 follow the farmers carry and lunges. Their legs paid for the stations, in other words, which is the fatigue signature the main report found in every cohort of the sport, amplified here by station work that took longer than it needed to. This reinforces the central diagnosis: even the running losses in this race are mostly station losses wearing running shoes.

The best-lap figure deserves its own sentence. A 5:34 kilometre in the middle of a Hyrox, ranked 87th of 547 teams, implies comfortably faster standalone speed, and the main report found that a single fast kilometre is one of the strongest predictors of overall potential in this sport (a correlation of 0.79 with the finish). The ceiling here is considerably higher than 1:51.

5 What fixing the stations would be worth

Everything above converges on one prescription, so it is worth pricing it precisely. Figure 6 takes their actual race and asks two hypothetical questions against the real finishing list of their event. First: what if they had closed half of the gap to the local median at each station and in the roxzone, with the running untouched? Their time becomes roughly 1:45, which would have placed around 224th, some seventy places higher. Second: what if every station had simply matched the local median, still with no running improvement at all? The time becomes about 1:39, around 177th, lifting them from the middle of the field into the top third, and, not coincidentally, to almost exactly the rank their running already holds on its own.

Concretely, the price list reads like this. The wall balls at 9:03 are the single largest item: bringing

Figure 6: Hypothetical finishes if the station and roxzone gaps to the local doubles median were closed, ranked against the actual event field. The running is left exactly as raced.

them to the local median of 5:18 is worth nearly four minutes, and wall-ball capacity is built with nothing more exotic than regular high-rep sets. The lunges (7:46 against 4:57) and the sled pull (7:41 against 5:05) are worth another two and a half to three minutes each and respond to leg strength and grip work. The roxzone’s 10:46, ranked 317th, holds about a minute of what the main report calls free speed, available for nothing but brisker walking and more decisive transitions. None of this requires becoming a different athlete; it requires the stations to stop being an afterthought in training. Their running took years to build. The thirteen minutes above can be bought in one focused off-season.

6 Full split sheet

The complete record is below, in race order, with each station’s event rank and the median of the Bengaluru men’s and women’s doubles fields alongside for reference.

Segment	Time	Rank	Local median
Run 1	6:16	–	
1km SkiErg	5:26	436	4:52
Run 2	5:34	–	
50m Sled Push	3:37	388	2:25
Run 3	7:53	–	
50m Sled Pull	7:41	484	5:05
Run 4	7:43	–	
80m Burpee Broad Jump	4:42	288	4:26
Run 5	6:02	–	
1km Row	5:22	206	5:27
Run 6	6:11	–	
200m Farmers Carry	2:34	437	2:07
Run 7	7:34	–	
100m Sandbag Lunges	7:46	471	4:57
Run 8	7:36	–	
Wall Balls	9:03	466	5:18
Run total (8 laps)	54:45	177	58:22
Best run lap	5:34	87	
Roxzone (transitions)	10:46	317	9:50
Finish	1:51:36	294	1:50:12*

Table 1: Full segment times, event ranks, and the local doubles median for comparison. Run laps carry no per-lap rank on the source sheet. The starred finish median is the mixed-doubles event median, 1:50:12.

In one line. A disciplined, negative-split race built on genuinely strong running, priced at thirteen minutes by stations that have not yet had the training attention the engine has, which is the most fixable diagnosis a Hyrox result can give.

A note on the data: this report combines the athletes’ published split sheet with field context from results scraped from Hyrox’s public servers. Mixed-doubles coverage in the archive is incomplete, and mixed teams carry no splits there, so station benchmarks use the Bengaluru men’s and women’s doubles fields (813 split records from the same event weekend) and field-size figures are close estimates rather than exact counts.
